Abstract: Intelligent energy saving system, the aim of the project is to save the energy or power, is use in places like home, libraries, industries etc. where lighting is very important. The aim of the project is use to save energy or power use in places like libraries where lighting is very important for the people who come to read books. So libraries will be well illuminated with many lamps. However, in this project work the basic signal processing of various parameters which are temperature, LDR, Relay, micro-controller etc.

Keywords: PIR sensor (Passive Infrared Sensor), LDR (Light Dependent resistance), Relay, Micro-controller, Temperature Sensor, Voltage Regulator IC.

1. Introduction

The development of any country depends to a large extent on availability and uses of electricity. We can generate electricity from renewable sources and help full for conserve non-renewable sources, renewable sources are not harmful for environment i.e. echoes friendly. All country required to conserve energy for upcoming generation to give them good life, so it’s very important to conserve electrical energy. Our aim is to conserved energy or save electrical energy. Nowadays, we can’t think our life without electricity as like food, cloth and shelter. In the world usage of electricity is increasing day by day because we do not have the awareness of the importance of electricity.

This is the reason of the increasing cost of managing, conserving and distributing. This problem also occurs everywhere in the world. The level of electricity usage is high especially at classrooms or library. Thus, this energy saving project will be created. When people use electrical devices Sometimes people forget to switch off the lighting appliances. That lost the energy i.e. electricity. Based on this problem, this energy saving project will be created using PIR sensor and LDR photo resistor. In this project we used the Passive Infrared Sensor (PIR sensor) to detect the body heat of humans. When the sensor detect nobody are in the lecture hall so the micro-controller counts the particular time in that particular time there are somebody coming into the lecture hall, the fans and the lighting system will reset its programme but if the hall stage empty the lighting system and air conditioner will turn off automatically. In our paper we try to save electrical energy because we know that population increases day by day and there needs also increases, so we need to save the electrical energy by using this system and we try to send a message to the world don’t miss use the electrical energy.

2. Material

A. Passive infrared sensor (PIR sensor)

A passive infrared sensor (PIR sensor) is a sensor to measures infrared rays (IR) light radiating from moving body of object. PIR sensor sense the heat of the object i.e. human body. The PIR sensor is the core part of the system. The system basically function based on infrared radiation, which is emitted from human body. PIR sensor is widely used in security system to detect the motion of human. Infrared (IR) light is electromagnetic radiation with a wavelength between 0.7 and 300 micrometres. Human beings are the source of infrared radiation. It was found that the normal human body temperature radiate IR at wavelengths of 10 micrometre to 12 micrometre.

Fig. 1. Infrared radiation of human body

B. LDR (Light Dependent resistance)

It stands for Light Dependent Resistor or Photo resistor, which is a passive electronic component, basically a resistor which has a resistance that varies depending of the light intensity. A photo resistor is made of a high resistance semiconductor that absorbs photons. It also based on the frequency of the photons. The total number of electrons is dependent of the photons frequency.

1) Description of LDR

The LDR resistance is increases as darkness is increases, almost high as 1MΩ but when there is light rays that incident
on the LDR, the resistance is decreasing to a few KΩ (10-20kΩ @ 10 lux, 2-4kΩ @ 100 lux) depending on the model. LDRs are very useful in many electronic circuits, especially in digital devices and more other. There are some audio application and sound system. It is used for turn ON or OFF a device according to the ambient light. On electroschematics.com we have some circuits that uses the photo resistor.

C. Relay

A relay is an electrically operated switch. A relay use an electromagnet to operate a switch mechanically, some other operating principles are also used, such as solid-state relays. Relays are used for controlling a circuit by a low-power signal. The relays is used in long distance telegraph circuits as amplifiers they repeated the signal come from one circuit and re-transmitted it on another circuit. Relays were used extensively in telephone exchanges and nowadays it use to perform logical operations in computers.

D. Microcontroller

A microcontroller is a small computer use in one integrated circuit containing a processor core, memory, and programmable input/output peripherals. A microcontroller is use and designed for embedded applications. Microprocessors used many computers and general use.

3. Block diagram description

As shown in figure (a) the block diagram, First the PIR sensor connected to the output of microcontroller will search for any human motion in the allocated area, if motion is detected then it will give logic 1 to the controller after this the temperature sensor connected to the controller will check the room temperature if the room temperature is below set value then it will turn OFF the fan else the fan will get ON, at the same time the LDR connected to micro-controller will check weather sufficient light is present, if sufficient light is not present then the LDR will turn ON the light else not.

4. Circuit diagram description

The PIR based efficient energy management system that would be activated when an occupant enters the target space. The PIR sensor absorbs the black body radiation emitted by that person and alerts the microcontroller which in turn operates the LCD display from standby to display the microcontroller receives signals from PIR and LDR sensor, depending on the ambient condition and lighting in the room and after some time lag (usually some few microseconds) operates the load drive to switch the load on or off. The LDR sensor helps in the checking of the lighting in the room and then regulates the ambient temperature that is being monitored. Whenever the light is adequate the lamp will go off and when the reverse is the case the lamp comes on. The thermostat sensor helps in room temperature measurement and as a result, the speed of the fan is varied according to the temperature readings from the thermostat. The LCD display will display the room temperature in degree centigrade, the status of the fan (i.e. Fan ON or Fan Off) and the status of the lighting (Light On or Light Off). The time delay set for the Microcontroller to check the PIR input is adjustable via the three push buttons provided to allow the varying of the time
delay by increasing or decreasing it through the following order: 10 sec, 30sec, 1min, 3min, 5min, 10 min and 30min. However, when the delay has lapsed and there is no more signal from the PIR sensor the microcontroller turns off the whole system.

6. Future works

In this PIR Sensor Based Security System, we have used low power, low cost PIR sensor that are easy to interface with other components. By using this system we were able to reduce the power consumed and memory space of the system.

7. Result

As per our survey in residential meter for stair cases, we came to know that with PIR we can save overall electricity cost about 86 per tube light as shown in table below.

### Approximate saving for staircases

In this project work we have studied and implemented complete working model using micro-controller. This work induces the study of energy saving in much application. By using or implementing this project we are looking for more power conversion and high security.

8. Conclusion

Intelligent energy saving system is not limited for any particular application, it is to be use anywhere in colleges, industries for small process modification in software coding according to the requirements. In future that our next generation will develop this energy saver system with wireless network. In our paper we connected the entire sensor to micro-controller with wire. This can be developed with wireless such that we place different sensor in different places. This sensor active the micro-controller with the signal instead of using wire. So we can decrease propagation delay time and cost of wiring.

Acknowledgment

We would like to thank Sharad Institute of Technology, Polytechnic, for facilitating and supporting us with the requirements to fulfil the project.
