Abstract: Solid waste management is emerging as a big environmental issue in the world and Srinagar city is no exception. The current status of solid waste management is poor because the best and most appropriate methods from waste collection to disposal are not being used. The increasing generation of solid waste and its inadequate management is affecting the scenic beauty of this historic place. As the management is done through traditional and obsolete methods the city is facing acute environmental degradation and visual pollution. The aim of this study is to study the collection and transportation system of Municipal Solid Waste in the city. The study reveals that there is acute absence of waste segregation at the source hence all types of materials are being disposed along with municipal solid waste which make waste handling very risky. Solid waste is being collected manually by the help of sweepers. They are normally using wheel borrows, hand carts for the collection of solid waste from the streets. At most of the collection locations solid waste containers are not available and the solid waste is dumped on ground. The generated solid waste from these locations is being collected by the help of open body vehicles irregularly. Storage containers are not compatible with the existing system. It was also observed during the investigation that number of containers and collection vehicles are not sufficient to handle the generated waste. The collection process is deficient in terms of manpower and vehicle availability. Bin locations were found to be inappropriate, thus contributing to the inefficiency of the system. Lack of suitable facilities (equipment and infrastructure) and underestimates of waste generation rates, inadequate management and technical skills, improper bin collection, and route planning are responsible for poor collection and transportation of municipal solid wastes. The lack of governance and inadequate infrastructures are the major constrains in designing a suitable MSW management plan of the city.

*Keywords*: Collection, Transportation, Municipal solid waste, Waste management.

## 1. Introduction

Srinagar, the summer capital of the state of Jammu and Kashmir in India, is situated in the western part of the state of Jammu and Kashmir and is in the northern region of India. Srinagar is located at 34° 8′ N, 74° 83′ E, 1730 m above sea level. Temperatures in Srinagar range from 10° to 30° (Celsius) during summer and -1° to 7° (Celsius) during winters and average annual rainfall in Srinagar is 650 mm. The city lies on both banks of the Jhelum River, a tributary of the Indus River. The city is famous for its lakes and houseboats floating over them. Tourism is the most significant segment of the city's economy. The city of Srinagar has been serving as a gateway to

some of the most scenic and beautiful places of the Indian subcontinent.

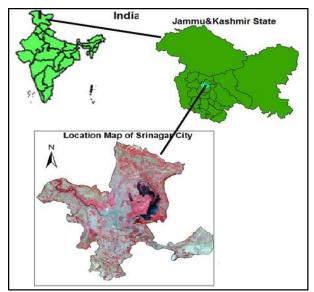

Fig. 1. Location of Srinagar City

Srinagar has a land area of approximately 279 Sq. Kms with a population of 12.03 lacs. Over the past two decades, MSW generation in Srinagar has increased tremendously from 180 tons in 1981 to 530 tons in 2011. This is largely as a result of rapid population growth and economic development in the country. The daily per capita generation of municipal solid waste in India ranges from about 100 g in small towns to 500 gm in large towns and in Srinagar it is 271 gm [1]. As per 2011 the city generated about 511 MT of solid waste per day while as around 260 MTs is being collected every day which is around 50 percent of the generated waste. However, the door to door collection facility has increased from only 23 percent in 2001 to 31 percent in 2011 to 60% in 2018. As per Solid Waste Management rules there should be 100% door to door waste collection. The generation of solid waste is growing in Srinagar due to growing population and inclusion of new areas. The city administration has been decentralized in 34 administrative wards with a total of 68 electoral wards in the city. Annexure 1 shows general ward wise information pertaining to area, population, generation, and shortage in each electoral ward of Srinagar City.

Solid waste needs to be managed in a sustainable way to reduce the overall burden on the environment. Solid waste management (SWM) is the major problem for many urban local bodies (ULBs) in India, as urbanization, industrialization and economic growth have resulted in increased municipal solid waste (MSW) generation per person [2]. The waste generation is growing with rapid urbanization and resultant population growth. The census population of Srinagar city, population projections, and waste generations details has been described in the table.

There are serious deficiencies in solid waste Management in Srinagar. Srinagar Municipal Corporation is responsible for collection, transportation, treatment and disposal of solid waste [3]. Effective solid waste Management is the major challenge of this city as there is no segregation of waste at source. There is an urgent need to move to more sustainable solid waste Management, and this requires new management systems and waste management facilities. Current solid waste Management system is inefficient; having a negative impact on public health, the environment and the economy. MSWM encompasses planning, engineering, organization, administration, financial and legal aspects of activities associated with generation, storage, collection, transfer and transport, processing and disposal of municipal solid wastes in an environmentally compatible manner adopting principles of economy, aesthetics, energy and conservation. MSWM involves activities associated with generation, storage and collection, transfer and transport, treatment and disposal of solid wastes however in most Indian cities the SWM system comprises only four activities, i.e., waste generation, collection, transportation, and disposal. Poor collection and in adequate transportation causes the accumulation of municipal solid waste at every nook and corner.

The waste management system should be based on the current as well as future quantities and characterization of wastes to determines the appropriateness of different waste management and treatment options.

The management of MSW is going through a critical phase,

due to the unavailability of suitable facilities to treat and dispose of the larger amounts of MSW generated daily in metropolitan cities. Adverse impact on all components of the environment and human health occurs due to unscientific disposal of MSW.

## 2. Waste collection

Waste collection is a critical component to waste management. The economic and environmental performance of the entire system can be impacted by the way that materials are collected and sorted. The collection point is an interface where waste generators and waste collectors meet and thus must be carefully managed if the system is to be effective.

Waste generators require waste collection with minimal inconvenience, while collectors must be able to collect waste in a way that is compatible with the planned treatment and processing methods if the waste management system is to be sustainable. The collection is very complex, difficult and costly process. Collection of solid waste typically consumes 60-80 per cent of the total solid waste budget of a community. Therefore, any improvement in the collection system can reduce overall cost significantly [4]. The collection practice adopted lacks "Segregation at source"- a practice mandated by SWMR 2016. Segregation is key to efficient solid waste management system as it separates out waste on the basis of its nature and characteristics, thus forming an important aspect that ensures efficient transportation, processing and treatment of waste.

#### A. Primary collection

The waste collection by Srinagar Municipal Corporation is very unorganized and unscientific. The vehicles used for primary collection at domestic level are wheel barrow, handcarts and tricycles. In the core areas of the city where the lanes are narrow only handcarts are used whereas in the outer areas, Hopper vehicles and tricycles are used. The wheel barrows and handcarts used by safai karamcharis are not maintained properly hence efficiency is reduced. Present design of handcarts is defective as the wheels of the cart are small and equipment is un-containerized. The capacity of the metallic handcart is only 28 kg and of wooden is 60 kg which are on lesser side; therefore, more number of trips is required for optimum efficiency [5]. These carts are not compatible with dustbins hence requires multiple handling and are unable to carry more waste. The sweeping and cleaning of city is done on the basis of a Single-tier system by forming "beats". In each beat there is one sanitation worker. Total numbers of sanitation

# International Journal of Research in Engineering, Science and Management Volume-3, Issue-4, April-2020 www.ijresm.com | ISSN (Online): 2581-5792

workers in 68 wards are 1041 and the total number of such "beats" in Srinagar city is about 2185.

Fig. 2. Handcart is not synchronized with secondary storage

The requirement of workers, tricycles and storage bins has not been calculated as per the actual requirement. There is also shortage of sweepers in the city. As per the requirement there should be 3751 workers but there are only 1041 safaikaramcharis. There is a total of 783 tricycles but for efficient solid waste management there should be 902 tricycles in the city and hence a shortage of 119 tricycles is there. Due to the shortage of workers and handcarts the area does not get cleaned daily as the shortage affects the performance of sweeper. Specifically shops / markets and other establishments, which normally start business after 9:30–10:00 AM and timing, do not synchronize with the work schedule of the sweepers, as by this time most of the collection procedure is over. Waste from these business communities again accumulate on streets and road as a result of which the city does not appear clean.

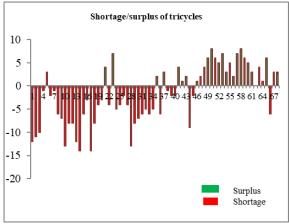

Fig. 3. Shortage/Surplus of Tricycles

The workers who are handling solid waste do not have any personal protection equipment's like uniforms, fluorescent jacket, hand gloves, raincoats, appropriate foot wear and masks. Double Handling of Waste is due to shortage of the infrastructure as handcarts are not properly distributed hence workers have to share the push carts. Double handling by the Sweeper for secondary transportation results in loss of productivity. Due to shortage of infrastructure there is only 60% door to door waste collection, the rest 40% remains uncollected on the streets.

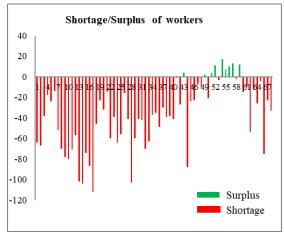

Fig. 4. Shortage/Surplus of Workers

# B. Secondary collection

Most of the secondary waste collection is carried out through street sweeping. The traditional system of collection is adopted by placing the communal bins at different points along the street corners and points along the roads. The distribution of secondary collection points is inappropriate and not as per requirement. The collection bins are neither properly designed nor properly located and maintained. Most of the waste generated from various sources such as residential, street sweepings, garden, parks, offices and shopping complexes is collected in same community bin. The waste is collected from total number of 512 collection points out of which 372 are open hence contributing to health and environmental hazards and only 140 are containerized. As per Solid waste management rules 1m<sup>3</sup> containers are required per 5000 population and hence 297 containers should be present but only 17 containers are present. The community bins are not washed at all resulting in unhealthy and unhygienic environment for users and workers. There is not periodic inspection of containers hence the floors, screen walls are damaged. Storage facilities have not been created and established by taking into account quantities of waste generation in a given area and distance required to be travelled by the waste collectors to deposit the waste at the storage facility.

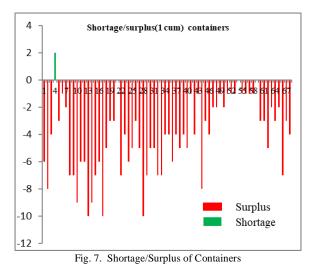

Fig. 5. Inappropriate secondary storage leads to deposition of waste outside the bin

Fig. 6. Inappropriate distribution of secondary storage points

The containers/collection points are located in a public place (lacking ownership by the public) which, in many situations, leads to indiscriminate disposal of waste outside the container. Thus, the actual economy of this system mostly depends on public co-operation. It is therefore essential to pay more attention to improving the design, and operation and maintenance practices of a communal system to increase public acceptance, and to optimize the productivity of this system. The Efficiency in this stage remains under achieved by issues related to placement of bins, littering around bins, non-lifting of bins as per schedule without adequate management controls, such systems fail resulting in street corner littering. The design of waste storage containers/depots (secondary collection points) is not synchronous with the design of vehicles deployed for both primary and secondary waste collection.

## 3. Waste Transportation

Transportation is the second important stage of solid waste management system. The waste is transported from dustbins and open collection points by tipper trucks and dumper placers owned by Srinagar Municipal Corporation. Transportation system does not synchronize with the positioning and type of community waste storage facility. Each tipper makes two to three trips a day to the disposal site, whereas dumper placer makes 8-10 trips a day with a capacity of 2.5-3.5 ton. The transportation system should be such that the waste should be collected at regular intervals at minimum cost.

Waste is not transported on a day to day basis leaving a backlog of waste to be transported. Transportation efficiency is affected due to uneven distribution of sweeper staff and nonsynchronization with vehicle arrival time. Many transportation vehicles are not fully covered or only partially covered by tarpaulin, which is against the guidelines of Supreme Court. Records for the exact distance travelled and the quantity transported are not maintained due to non-functional milometer in the vehicles. There is almost negligible monitoring of transportation vehicles regarding the running of vehicles, operation and maintenance, fuel distribution and disposal control. Vehicles of Srinagar Municipal Corporation are not repaired regularly and no routine maintenance system exists. The vehicle operation is normally in single shift. Old vehicles, which have already outlived their economic life and utility, are still the part of SMC operative fleet. In the old city, day time lifting of solid waste has always been problematic. There are no fixed routes; drivers on their own have fixed the collection routes based on their experiences. There is no routing plan for waste collection in the city. Drivers on their own have fixed the collection routes based on their experiences. The tipper trucks required is 170 but after the waste is segregated at the source the capacity of the trucks will increase and hence only 61 trucks are required out of which 32 will be for biodegradable, 9 for recyclable and 20 for inert waste.

The types of vehicles used for transportation does not synchronize well with containers placed at depots or transfer stations hence multiple handling of waste occurs. The selection of the type of vehicles does not reflect the quantity of waste to be transported, travel distance, road widths, road conditions etc.

# 4. Conclusion

The total elimination of the waste is an impractical suggestion, rather than it should be managed in an effective manner. The municipal solid waste management system is the most poorly rendered, the systems applied are unscientific, outdated and inefficient. Poor conditions of containers, inadequate maintenance and non-replacement of worn-out collection vehicles contributed to behaviors such as littering and illegal dumping by citizens leading to insanitary living conditions. Poor management of finances and resources, and laxity among employees (leading to inconsistent service) were major contributing factors to mismanagement of solid waste. Infrastructural problems are the main impediment to sustainable waste management and should be the first priority for municipalities to improve waste collection and disposal. Inadequate service coverage and operational inefficiencies of services including an unskilled workforce is another major set of challenges faced by municipalities in providing sufficient waste services to citizens. Ineffective Technologies and Equipment, poor conditions of containers, inadequate

maintenance and replacement of worn-out collection vehicles contributed to behaviors such as littering and illegal dumping by citizens as some feel that they could not properly dispose of trash because trash bins and waste services are not properly maintained.

Municipal authorities that are responsible for managing MSW have budgets that are insufficient to cover the costs associated with developing proper waste collection, storage, treatment and disposal. The lack of strategic MSW plans, waste collection/segregation and a government finance regulatory framework are major barriers to achieving effective SWM in India. Limited environmental awareness combined with low motivation has inhibited innovation and the adoption of new technologies that could transform waste management in India. Public attitudes to waste are also a major hurdle to improving the waste system. Information on future quantities and characterization of wastes is essential as this determines the appropriateness of different waste management and treatment options. State-level procurement of appropriate equipment, vehicles and machinery is necessary for primary and secondary collection with effective systems for monitoring collection, transport and disposal. Waste management must involve waste segregation at source to allow much more efficient value extraction and recycling. Separating organic and inorganic waste would have significant benefits and should be the responsibility of the waste producer.

The municipalities need to invest more resources into a

smaller but more skilled group of personnel instead of wasting money on a large but inefficient and ineffectual workforce. The local authorities should increase the number and optimize the distribution of litterbins on the streets and other public places as a measure to discourage people from littering. Solid waste management needs to be efficiently provided to the community to maintain aesthetic and public health standards. They should increase the number and optimize the distribution of litterbins on the streets and other public places as a measure to discourage people from littering. Municipal laws should have adequate provisions to deal effectively with the ever-growing problem of solid waste management to improve the system through proper and suitable planning.
